## Field Evaluation of Almond Varieties

---

---

**Project No.:** 14-HORT2-Lampinen

**Project Leader:** Bruce Lampinen  
Department of Plant Sciences  
University of California, Davis  
One Shields Ave.  
Davis, CA 95616  
530.752.2588  
bdlampinen@ucdavis.edu

**Project Cooperators:** Tom Gradziel, Sam Metcalf, William Stewart, Maria Contador, and Mary Ann Thorpe, UC Davis  
Joe Connell (emeritus), UCCE - Butte County  
Dani Lightle, UCCE – Butte/Glenn/Tehama Counties  
Roger Duncan, UCCE - Stanislaus County  
Gurreet Brar, UCCE - Fresno/Madera Counties  
Mario Viveros and Minerva Gonzalez, UCCE - Kern County  
Chico State University  
The Billings Ranches, Kern County

### **Objectives:**

The first objective of this project is to evaluate performance of pollenizers and Nonpareil clones in a replicated field trial in McFarland California. The second objective is to use the replicated data on light interception and yield to assess the relative productivity per unit of light intercepted for the Nonpareil clones, varieties and selections. The third objective is to initiate the next generation almond variety trials.

### **Interpretive Summary:**

Yields at the McFarland trial continue to be high compared to the 1993 regional almond variety trials. The McFarland trial reached an average production of 3000 kernel pounds per acre in the 5<sup>th</sup> growing season which was six years earlier than the 1993 Kern RAVT while neither the 1993 Butte nor the 1993 Delta trials ever reached this level of production. In order to develop the canopy this quickly, water and other inputs need to be high and this has resulted in high disease pressure (especially hullrot). Because this trial is replicated, unlike the earlier regional almond variety trials, we have the opportunity to more accurately assess yield differences among the Nonpareil clones, varieties and selections. In addition, because we have detailed light interception data, we can assess whether differences in productivity among varieties and selections are due to faster canopy growth or higher productivity per unit light intercepted. Nonpareil yields varied from 4300 to almost 5000 kernel pounds per acre in 2011 and continued to be generally higher than pollenizer yields. In 2012, yields were down substantially compared to 2011, most likely due to alternate bearing. In 2013, yields increased but were not as high as 2011. Yields in 2014 were still quite high. There appears to be

some separation of cumulative yields for the Nonpareil clones with Nonpareil-Nico highest and Nonpareil-5, Nonpareil-6 and Nonpareil-Jones all having significantly lower cumulative yields. Hull rot continued to be the major disease related problem with the highest levels in 2-19e and Kochi with the Nonpareil clones having intermediate hull rot pressure. Hull rot pressure was minimal in 2013 and 2014. Summary data from the 2006 to 2014 seasons shows that although bloom period varied significantly from one year to the next, in general, overlap of Nonpareil bloom with pollenizers was good in all years.

The next generation of Regional Almond Variety Trials was planted in the winter of 2014 in Butte (Chico State University), Stanislaus (Salida School District Site), and Madera (Chowchilla grower site) counties. Nonpareil was alternated with 30 varieties and/or selections at all 3 sites. Trees at the Butte, Stanislaus and Madera trial were planted on Krymsk 86, Nemaguard and Hansen 536 rootstocks respectively (with the exceptions listed at the bottom of **Table 5**). Unlike the previous generation Regional Almond Variety Trials, there are four replications of each of the varieties and selections at each of the three sites in the 2014 trials.

## **Materials and Methods:**

### McFarland Variety Trial

This report will concentrate on a replicated variety trial of eight varieties and eight Nonpareil clones that was planted in 2004 in Kern County near McFarland. Soils at the site consist of McFarland loam and Wasco sandy loam (both Class I soils). The irrigation system is double line drip. Tree spacing is 20 feet between tree rows and 18 feet between trees for a density of 121 trees per acre. Varieties planted included Chips, Kahl, Kochi, Marcona, Selection 2-19e, Sweetheart and Winters. Nonpareil clones planted include Nonpareil 3-8-2-70, Nonpareil 5, Nonpareil 6, Nonpareil 7, Nonpareil Dr., Nonpareil-J, Nonpareil-Newell and Nonpareil-Nico. There are six replications of each variety and Nonpareil clone with 34 trees per replication. Pollenizer and Nonpareil rows alternate in the orchard.

In 2014, data was collected on bloom and maturity timing, disease pressure (scab, *Alternaria* and hull rot), yield and midday canopy light interception. In 2006, 2007 and 2008, midday canopy light interception was measured manually using a hand lightbar. The mobile platform light bar (described in report for Almond Board project titled “Development and Testing of a Mobile Platform for Measuring Canopy Light Interception and Stress in Almond”) was used to measure midday canopy light interception at the McFarland trial in 2009-2014.

### 2014 Regional Almond Variety Trials

The next generation almond variety trials were planted in the winter of 2014 in Butte (Chico State University), Stanislaus (Salida School District Site), and Madera (Chowchilla grower site) counties. The varieties and selections planted are listed in **Table 5**. The first 31 items are common to all 3 sites and a few different items added at individual sites are listed at the bottom of **Table 5**. Trees at the Butte, Stanislaus and Madera trial were planted on Krymsk 86, Nemaguard and Hansen 536 rootstocks

respectively (with the exceptions listed at the bottom of **Table 5**). Trees were planted at a spacing of 18' x 22' at the Butte site (110 trees/acre), 16' x 21' at the Stanislaus site (130 trees/acre) and 12' x 21' at the Madera site (173 trees/acre). This density is significantly higher than the previous generation RAVTs where planting densities for the Butte, San Joaquin and Kern trials were 64, 75 and 86 trees/acre respectively.

## Results and Discussion:

### McFarland Trial

The grower started ripping every other row center in 2009 and this has resulted in significant improvements in water penetration in the orchard. This procedure has continued and appears to be beneficial with much better water penetration observed.

Weather during bloom was generally good at the McFarland trial site. For the 2014 bloom period there were 146 good bee flying hours (temperature  $\geq 59^{\circ}\text{F}$ , windspeed  $\leq 10$  MPH, and no rain). This compared to 182, 91, 58, 94, 103, and 175 good bee flying hours in 2008, 2009, 2010, 2011, 2012 and 2013 respectively.

Although the absolute date of bloom for all varieties varied from year to year, bloom overlap among the Nonpareil clones and pollenizers was good in every year (**Figure 2, 3**). Although the bloom dates vary considerably from year to year, the relative bloom dates among the Nonpareil versus pollenizers all appear to shift together. Average bloom dates for the 2006 to 2014 seasons are shown in **Figure 4**.

Hullsplit progression or 2010-2013 is shown in **Figure 5**. In 2014 hullsplit initiation and completion was earlier than average by about 2.5 weeks (**Figure 6**). This is the earliest we have observed during this trial to date. The average hullsplit progression for 2006 to 2014 is shown in **Figure 7**.

In 2010, scab was only observed on Winters and Nonpareil-5 and in 2011 on Winters and selection 2-19e (**Table 1**). In 2012, scab was present at low level on most varieties and selections. In 2013, scab was present only in Kahl, Marcona and Winters and in 2014 only in Kochi and Winters (**Table 1**). *Alternaria* was not present in 2010 but in 2011 and 2012 all Nonpareil selections and pollenizers had some present with the worst being in Kahl, Winters, Kochi and Marcona (**Table 1**). In 2013, *Alternaria* was not observed in Nonpareil selections but was present in Sweetheart, Chips, Kahl, Marcona and Winters (**Table 1**). In 2014, *Alternaria* was worst in Winters, Kahl, Sweetheart and Marcona (**Table 1**). Hullrot continued to be the main problem at this site. There was substantial hullrot in all varieties and selections with the most severe disease pressure in Kochi and Winters in both 2010 and 2011 (**Table 1**). Kochi also displayed severe hullrot in 2008 and 2009. There was also substantial hull rot in all the Nonpareil clones in 2010 and slightly less in 2011(**Table 1**). Overall, hull rot levels decreased from 2012 to 2014, with 2014 showing the lowest presence in five years (**Table 1**).

Yield data for the McFarland trial from the 2006 through 2014 seasons are shown in **Table 2, 3 and 4**. All of the Nonpareil clones have tended to have higher cumulative yield compared to most of the pollenizers (**Table 4**). Among the Nonpareil clones, there is some separation regarding cumulative yield with Nonpareil Nico, Nonpareil 38270

and Nonpareil Newell having the highest cumulative yields (**Table 4**). Selection 2-19e (Kester) has had the highest cumulative yield among all of the pollenizers in the trial followed by Winters (**Table 4**). The replication provided in this trial adds much value to the data compared to earlier unreplicated variety trials but it comes at a cost in terms of the time required for maintaining, rating and harvesting the plots.

The yields from this trial continue to be high for the age of the orchard. **Figure 1** shows average yield by orchard age for all varieties, selections and Nonpareil sources for the Butte, Delta and Kern trials planted in 1993 compared to the McFarland trial planted in 2004. The McFarland trial reached an average production of 3000 kernel pounds per acre six years earlier than the 1993 Kern RAVT while neither the Butte nor Delta trials ever reached this level of production (**Figure 1**). Yields have tended to alternate around 3700 kernel pounds per acre for the past few years which is what would be expected based on light interception levels.

The productivity per unit canopy light interception was quite high for the size of the tree in 2009 (ranging from 52 to 85 kernel pounds per unit light intercepted) and was still fairly high in 2010 (ranging from 23 to 51 kernel pounds per unit light intercepted) since our previous data has suggested 50 kernel pounds per unit light intercepted is near the normal maximum for almond (**Table 3**). In 2011, yield per unit light intercepted averaged 74.8 for the Nonpareil clones and 40 to 65 for the pollenizers (**Table 3**). This trend towards yield per unit PAR intercepted in the range of 50 has continued in 2013 and 2014 (**Table 4**). **Figure 8** shows the yield per unit PAR intercepted by variety or selection for all years of the study (data for Nonpareil sources are averaged). This figure suggests that the yields tend to alternate around 50 confirming our earlier observations. Nonpareil has produced above the 50 line while the clones have averaged below the line.

#### Next Generation Almond Variety trials

The Butte, Stanislaus and Madera sites were planted in the winter of 2014 as described in the Materials and Methods section. See **Table 5** for a list of items planted at the trials. Bloom, hullsplit and yield data collection will begin in 2016. All of the sites are growing well and although the Chico trial was short about 60 trees from the nursery at planting and some trees were lost at all 3 sites, they have mostly been replaced.

#### Acknowledgements:

The authors wish to thank the Almond Board of California for their continued support of this project. We also want to thank the Billings Ranches for their excellent cooperation in managing and maintaining this trial. In addition, we would like to thank Chico State University/Jeff Boles, the Salida School District/Lane Parker as well as the Creekside Farming Company for their cooperation on the next generation variety trials.

**Figure 1.** Average yield for all varieties, selections and Nonpareil sources by orchard age for the 1993 Butte, Delta and Kern Regional Variety Trials as well as the McFarland Variety Trial that was planted in 2004. Number in parenthesis after trial name is number of trees per acre.

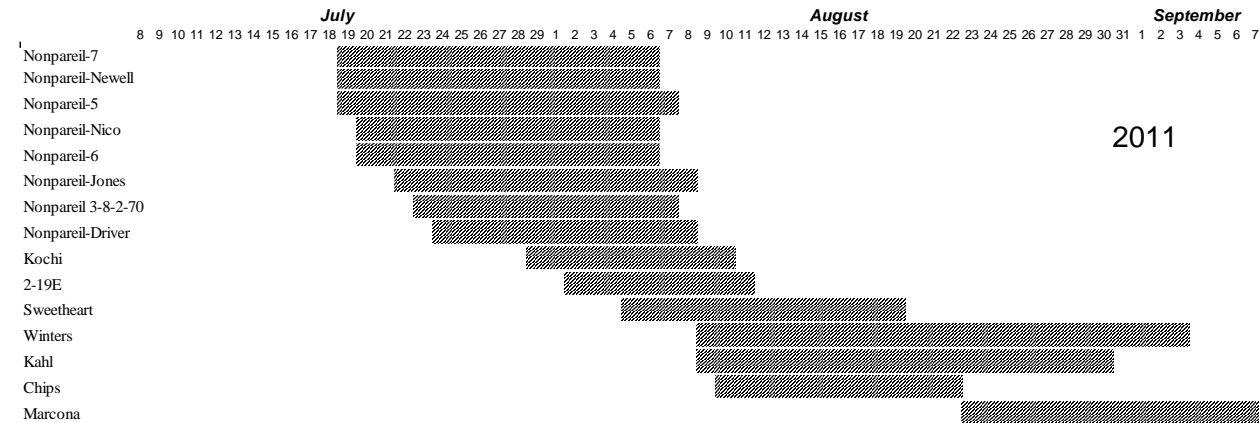

**Figure 2.** Bloom data for the McFarland Trial for the 2010-2012 seasons. Cross hatched area indicates onset of bloom to 100% petal fall. "F" indicates full bloom.

**Figure 3.** Bloom data for the McFarland Trial for the 2013 and 2014 seasons. Cross hatched area indicates onset of bloom to 100% petal fall. "F" indicates full bloom.

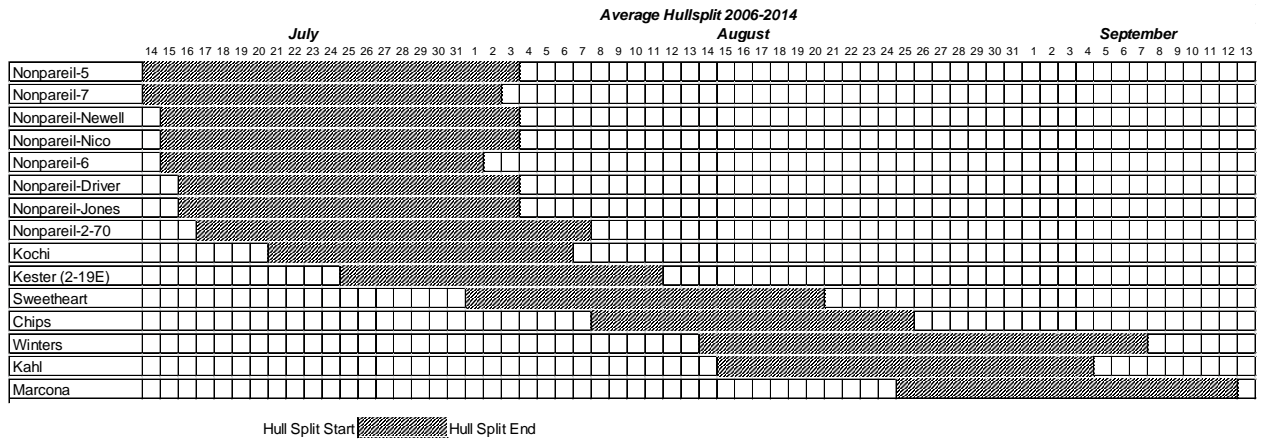

**Figure 4.** Average bloom data (2006 to 2014) for the McFarland Trial. Cross hatched area indicates onset of bloom to 100% petal fall. "F" indicates full bloom.

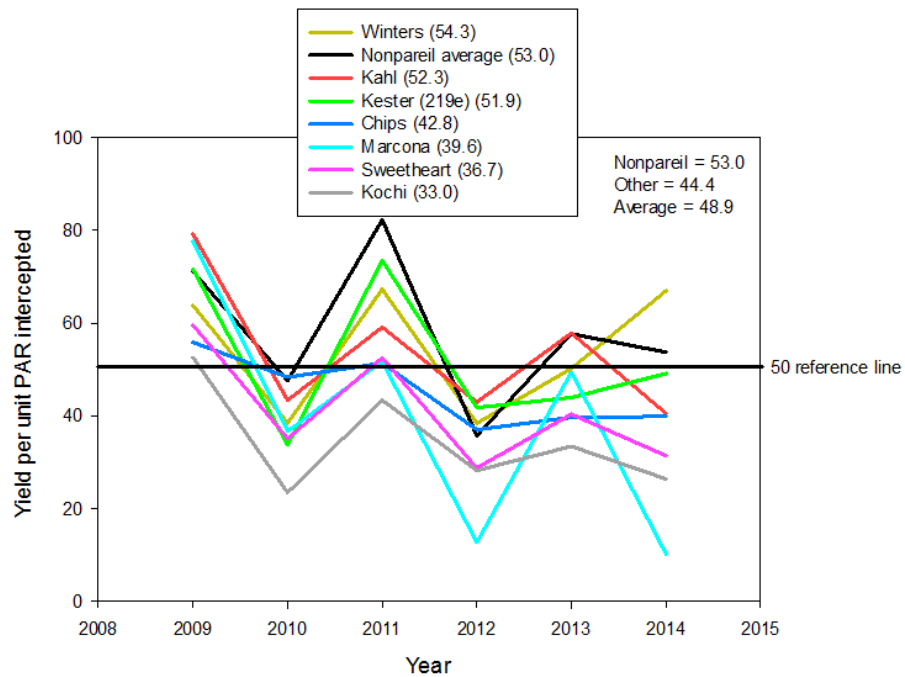

**Figure 5.** Hull split progression for the McFarland Trial for the 2010-2013 seasons. Cross hatched area indicates onset of bloom to 100% petal fall. "F" indicates full bloom.

**Figure 6.** Hullsplit progression by variety and Nonpareil source for 2014 season at the McFarland trial.

**Figure 7.** Average hullsplit progression by variety and Nonpareil source for 2006 to 2014 seasons at the McFarland trial.

**Figure 8.** Yield per unit PAR intercepted by variety and year (kernel pounds per 1% light intercepted). Number following variety name in legend indicates the five year average value. Average for all varieties and years was 49.3. A value of 50 is what we have found the best orchards can average over several years.
